

Influences of large scale circulation and atmospheric rivers (ARs) on US winter precipitation beyond ENSO

Goal 1 : Underlying mechanism of large scale circulation control on atmospheric rivers (AR) and precipitation variability across the US during winter (DJFM) in observations

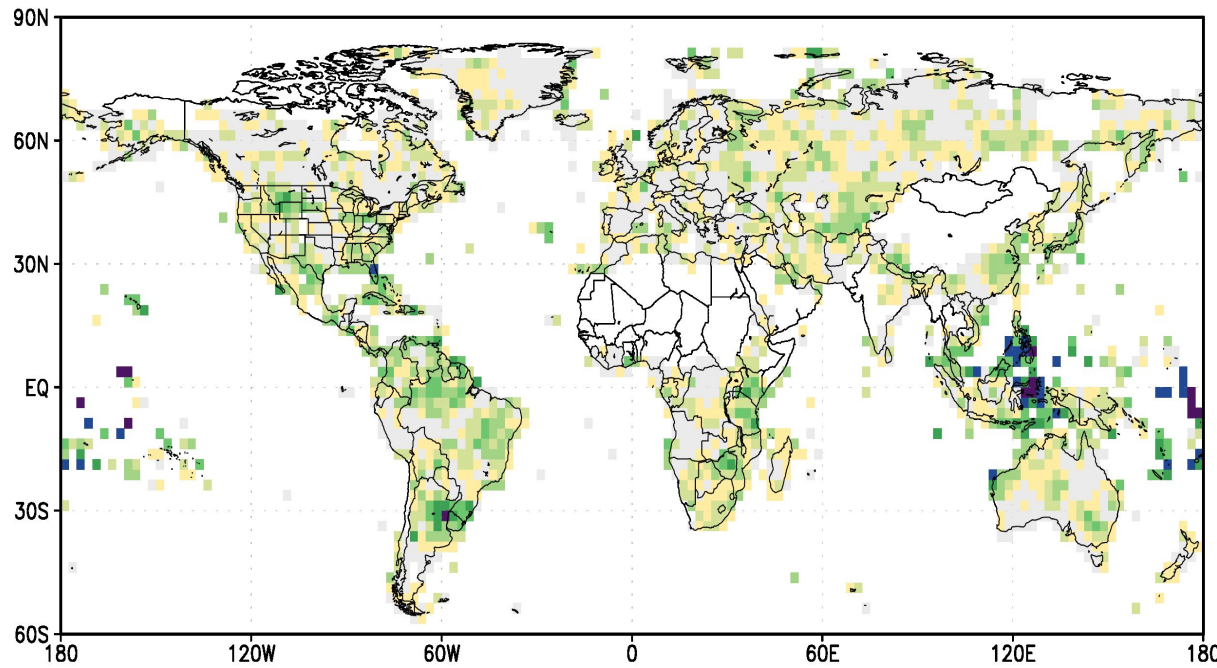

Goal2: How climate models (CFSV2 and CESM2) replicate these observed processes and mechanisms

Path forward

How large scale circulation patterns determine precipitation via Atmospheric Rivers (ARs)?

Online sources

Mean states (jet, precipitation and ARs) in ERA5 and CESM2 (1940-2023)

a DJFM U200 (mean state in Obs)

b DJFM ARs/rainfall (mean state in Obs)

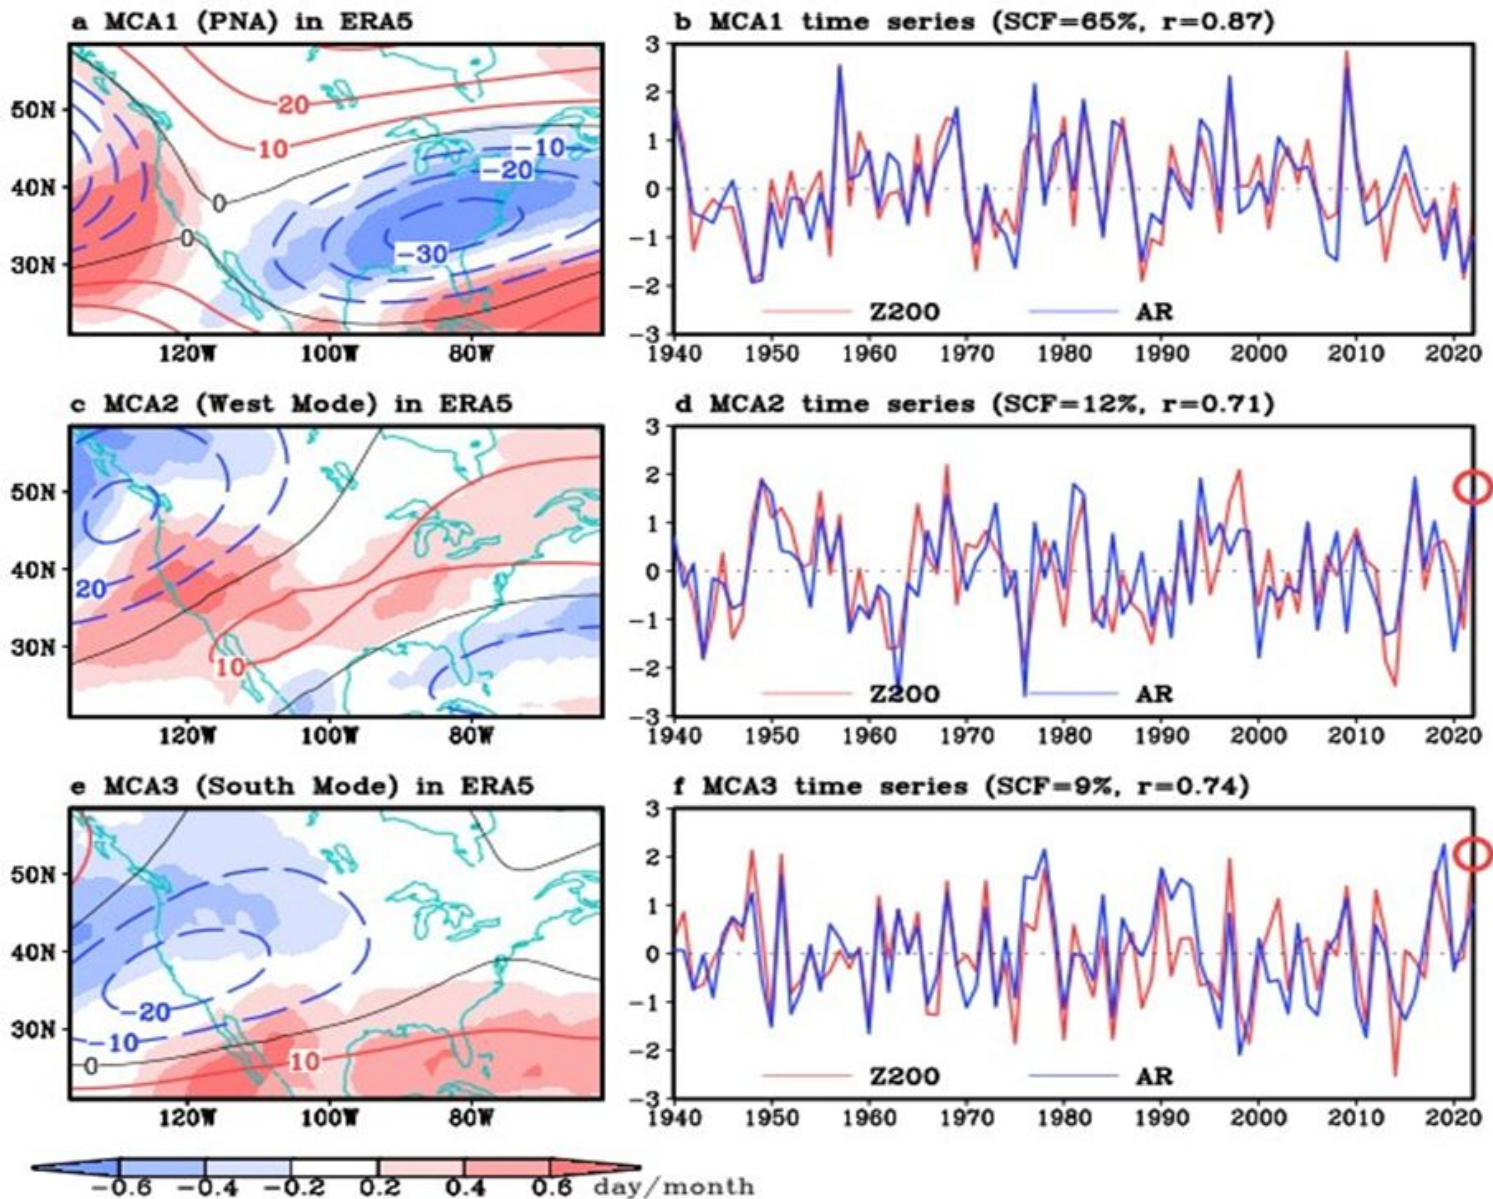

c DJFM U200 (mean state in CESM2)

d DJFM ARs/rainfall (mean state in CESM2)

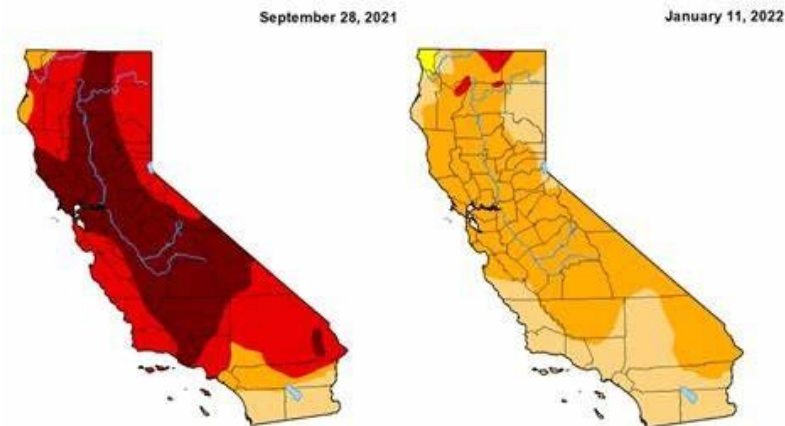

Large scale circulation modes influence precipitation through regulating ARs

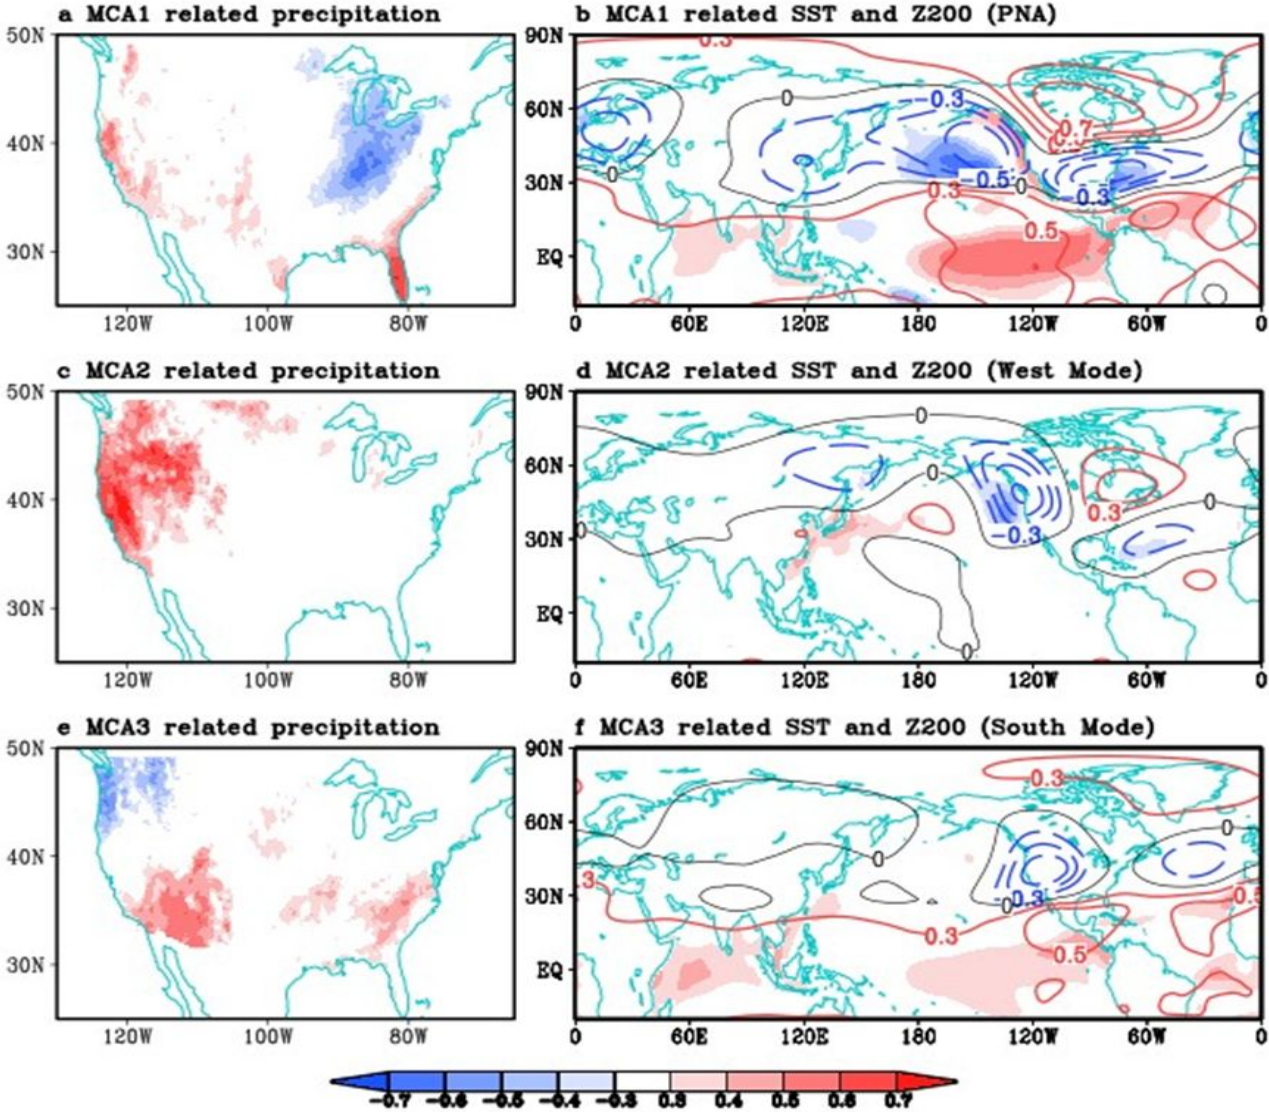

Sep 2021

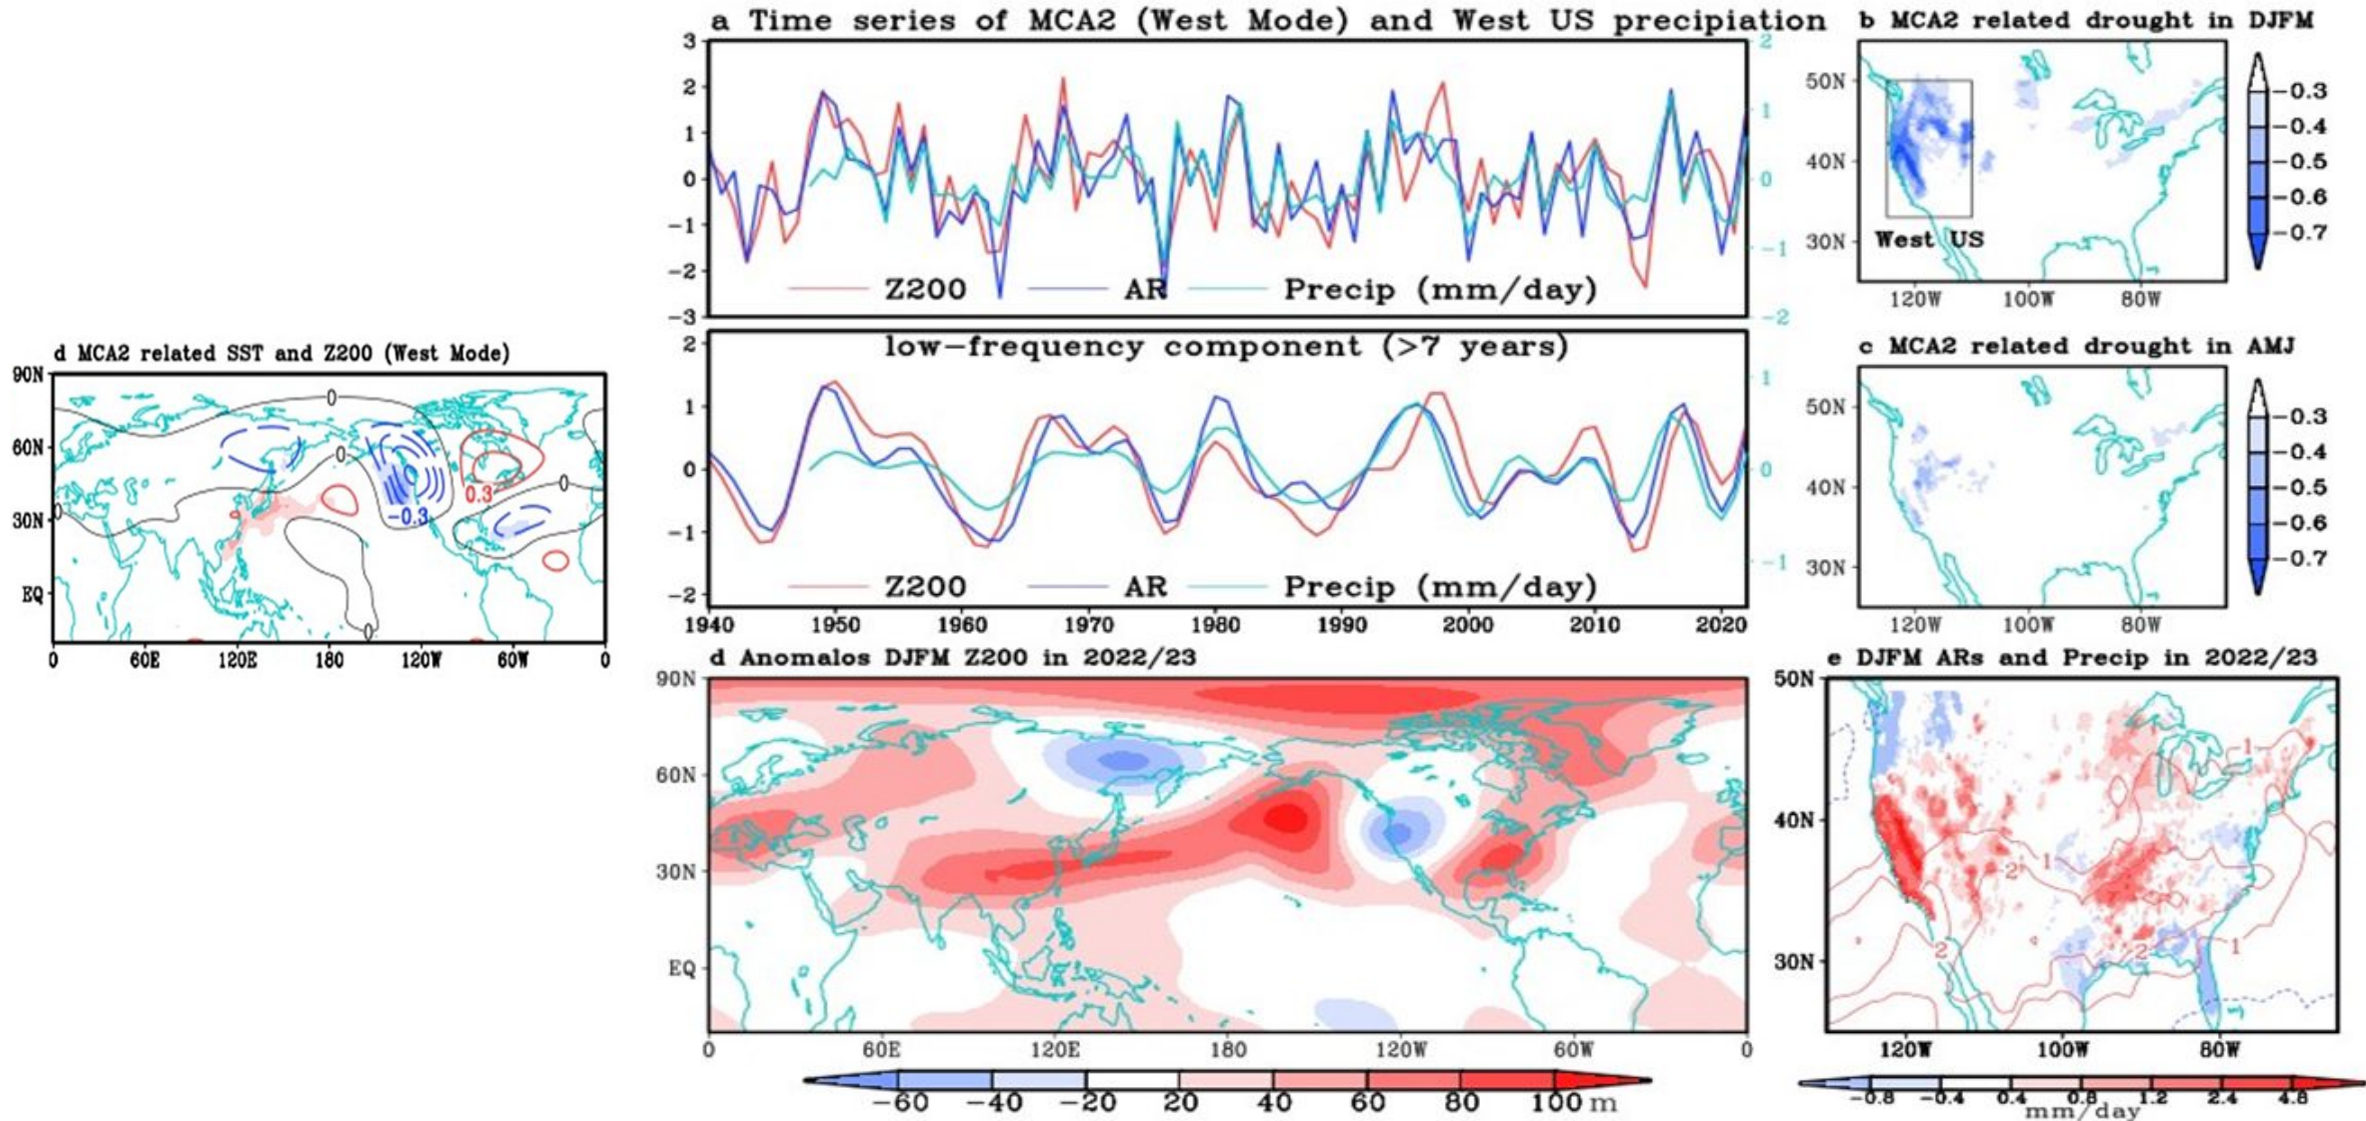

Jan, 2022

Despite ENSO's dominance, its effects on precipitation remain limited

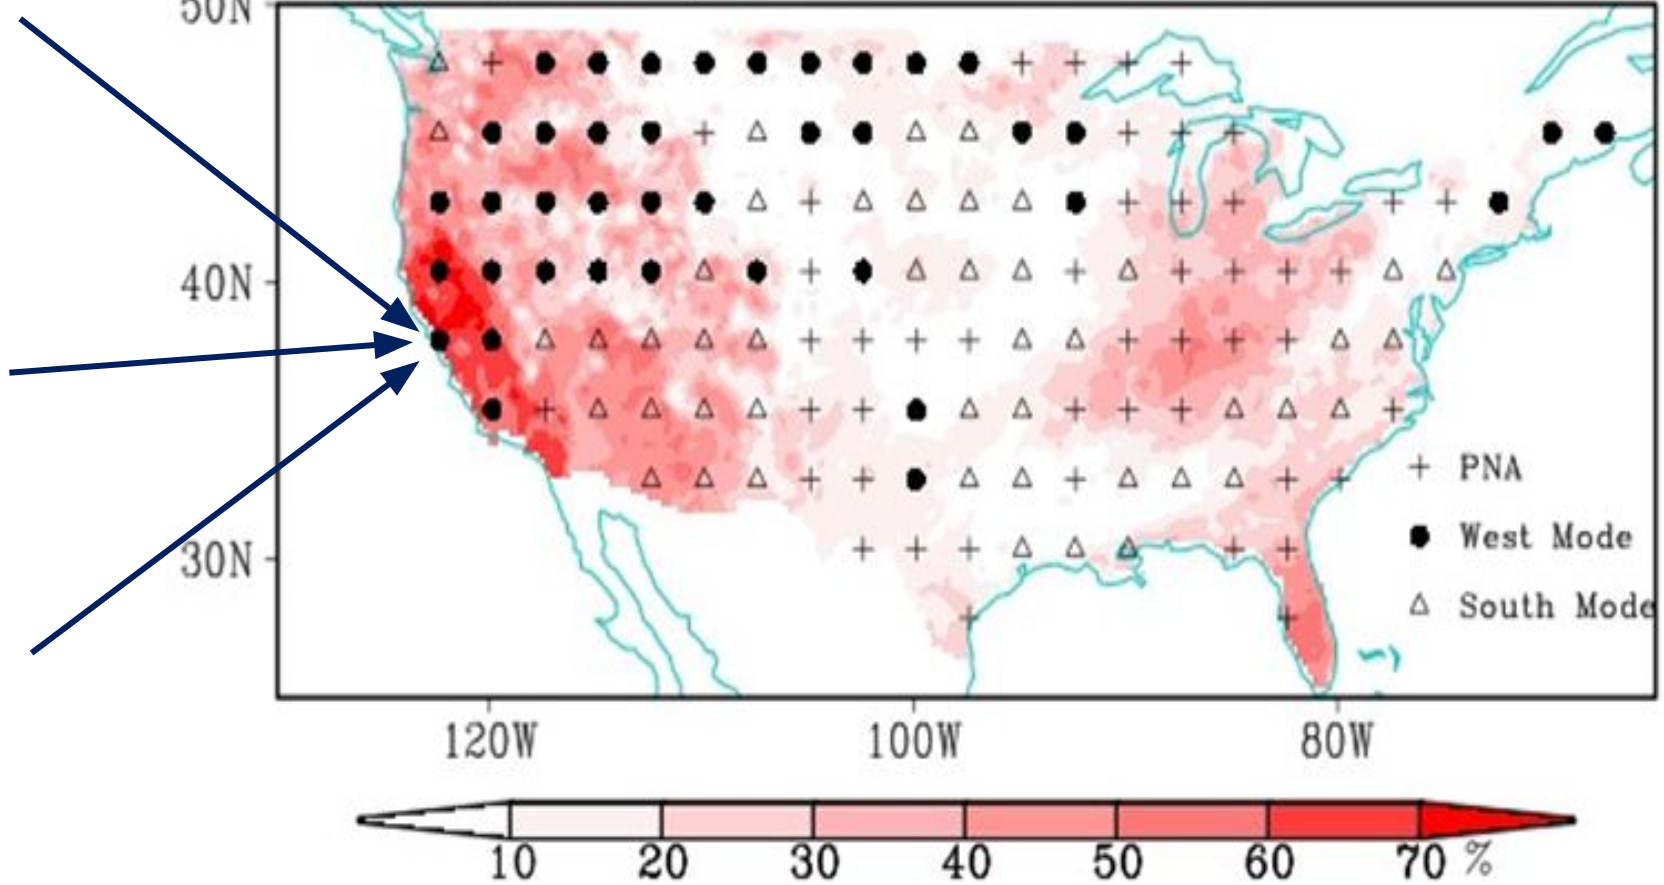

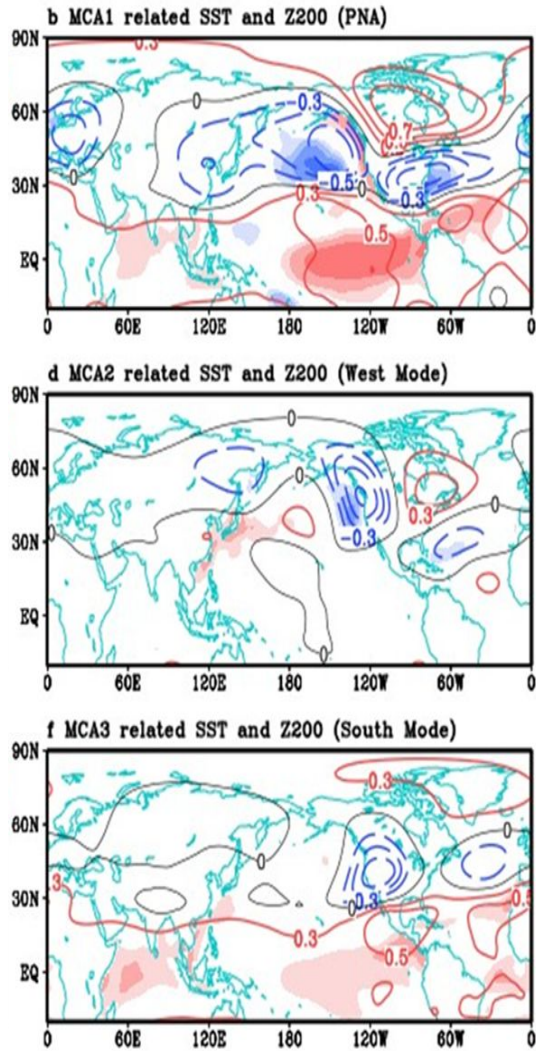

West Mode demanding more attention

The three circulation modes provide us with some capability to “predict” precipitation

$$\text{Precipitation (each grid)} = a \times \text{PNA} + b \times \text{West Mode} + c \times \text{South Mode}$$

Capability of regression models

West Mode : Internally driven

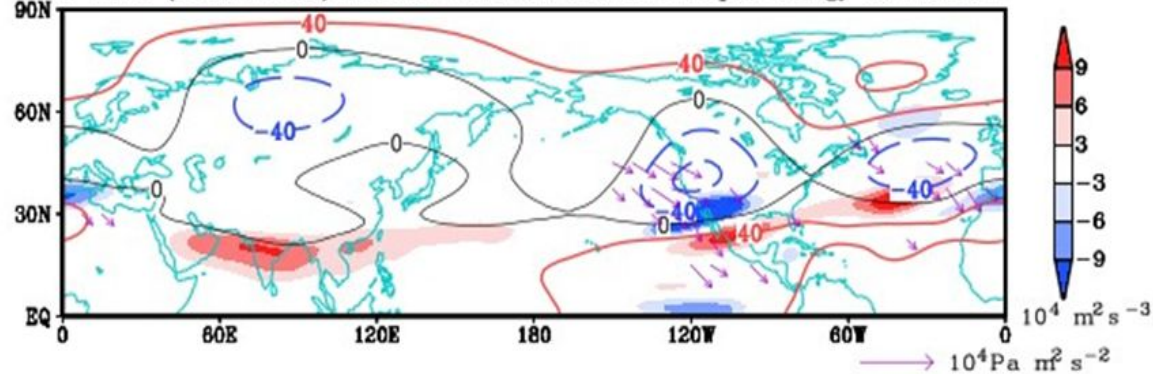

a MCA1 (PNA) related waveflux and barotropic energy conversion

b MCA2 (West Mode) related waveflux and barotropic energy conversion

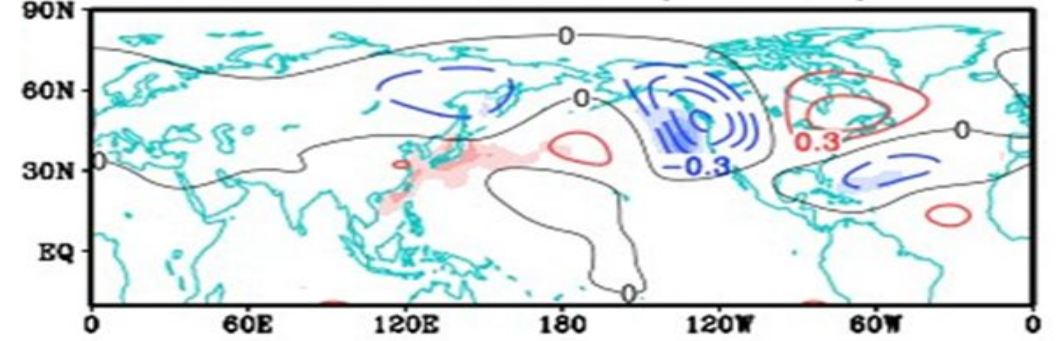

c MCA3 (South Mode) related waveflux and barotropic energy conversion

b MCA1 related SST and Z200 (PNA)

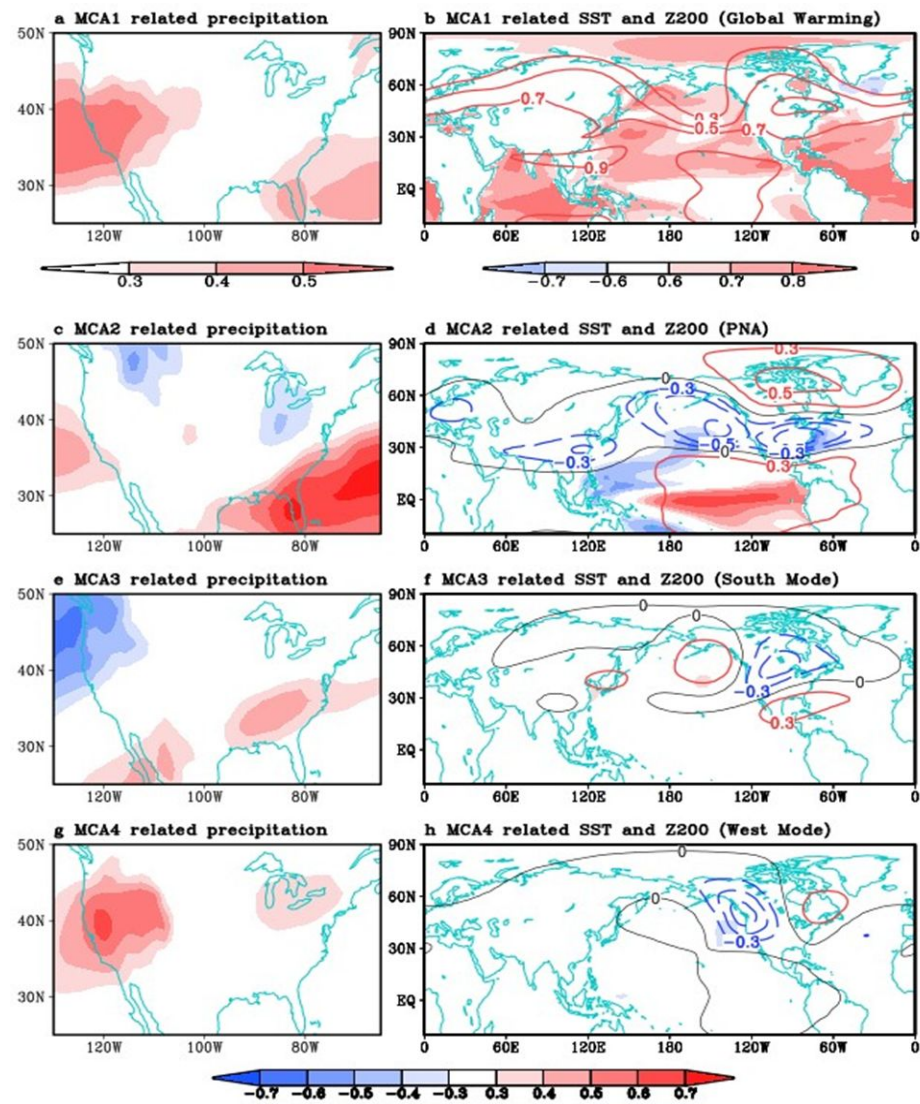

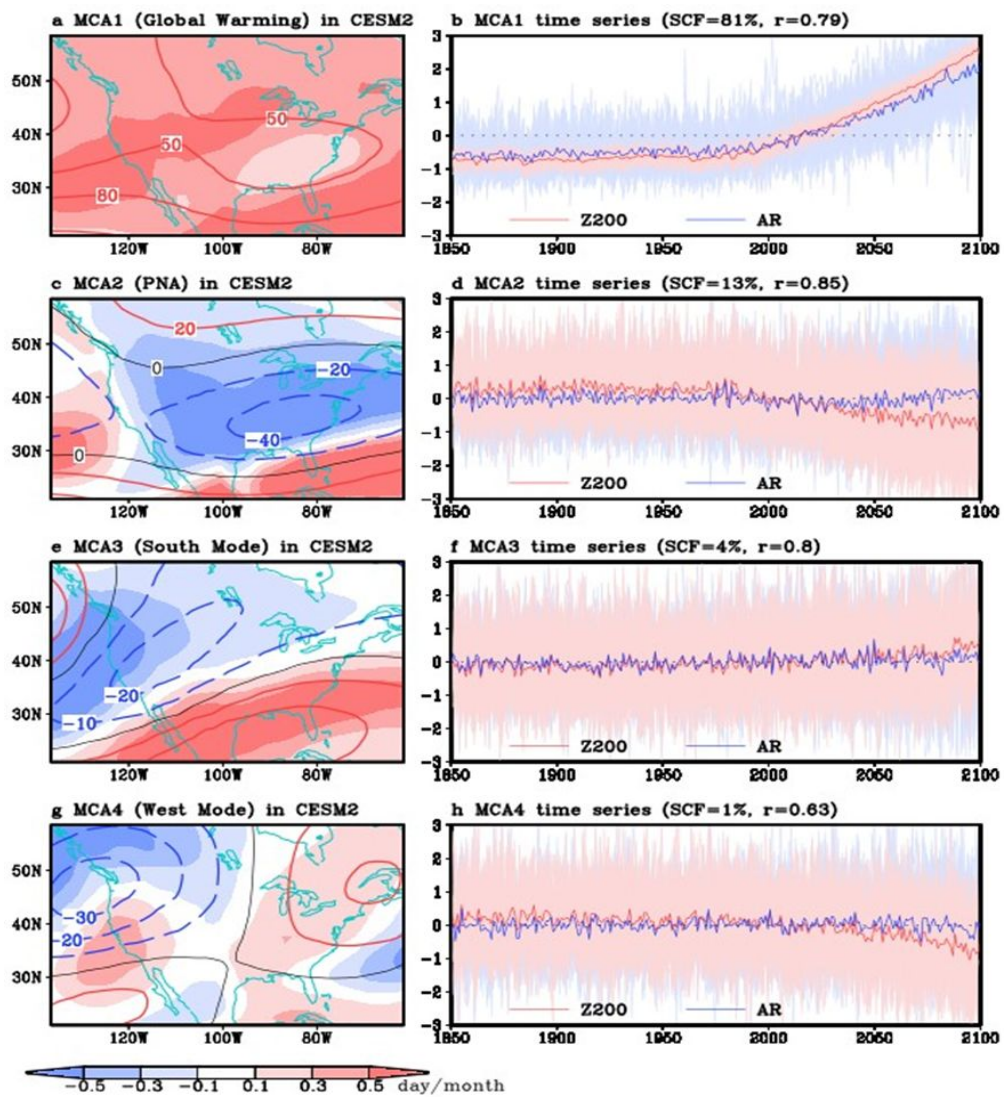

d MCA2 related SST and Z200 (West Mode)

f MCA3 related SST and Z200 (South Mode)

Future precipitation changes have some degree of climate resilience

Limitation of CFSv2 in replicating the observed circulation-AR relationship

Take-home messages

Two leading circulation modes in winter together explain almost 70% of CONUS precipitation in the Western US and 30% in the Central and Eastern US.

One of these modes is a well-known teleconnection modulated by ENSO, and the other reflects internal variability related to jet stream dynamics.

This internal mode is more critical than the ENSO-driven one in regulating precipitation changes through mediating ARs over the CONUS, particularly in the West.

Precipitation changes over the CONUS may be partially stochastically driven and, therefore, own some resistance to global warming in the decades to come.
