#### HAWAII PACIFIC AVIATION WEATHER SAFETY WORKSHOP

#### Mountainous Environment Hazards to Rotary Wing Operations

Vitalie Gumeniuc

June 09, 2023

#### *High Altitude Wind Turbulence*

### What is a Designated Mountainous Area?

#### **14 CFR Chapter 1 Subpart B—Designated Mountainous Areas** (Est. 1956)

• § 95.19 Hawaii Mountainous Area. (Est. 1962, Amended 1963)

#### Definition:

 Designated mountainous areas include those areas having a terrain differential exceeding 3'000 feet within 10 nautical miles within those one arc-second quadrangles overlying terrain or U.S. territorial waters.

An area used to identify a terrain elevation differential exceeding 3,000 ft within:

- **1.** A 10 NM radius from a specified point ("*Grid Method*"); or,
- **2.** 10 NM from the centerline of a route or transition ("*Route Method*").

# **High Altitude**

- High Density Altitude
- Reduced lift capability
- Reduced engine performance
- Degraded overall maneuverability
- Landing distances are lengthened
- Load capabilities and rates of climb are reduced
- OGE power may not be available
- Accidents resulting from High Density Altitude and High Gross Weight are a major contributing factor for Army Aviation aircraft losses.

### Origin of wind and its causes

- Atmospheric pressure and temperature variations cause the air to move in two ways: ascending and descending currents (vertical motions) and the horizontal flow of air known as wind.
- Currents and winds or atmospheric circulation cause weather changes.
- Knowledge of the wind is essential for navigation, fuel management, load capabilities and flight safety purposes.

#### **Origin of wind and its causes**

• In mountainous terrain, the winds are categorized into three types:

**Prevailing** - Upper-level winds.

*Convective (local or valley)* - Lower-level winds.

**Surface winds** – Layer of air lying close to the ground, less turbulent.

### **Prevailing wind**

- Large scale direction and velocity of air mass movement.
- Generally, flows in horizontal fashion.
- Normally from northeast (trade winds) in Hawaii.

### Convective winds (local or valley)

- Created by convection heating and cooling.
- Unstable air.
- Generally, flows parallel to larger valleys.
- Day up flow / Night down flow.

### **Convective winds (valley)**

### Wind zones

# Summary

- Winds can often be dramatically different than forecast.
- Wind near surface often different than upper-level wind.
- The wind direction and velocity can change rapidly in mountainous terrain.
- Reduced Visibility: Mountains can generate weather phenomena such as fog, low clouds, or precipitation.

#### **Turbulence and its causes**

- Turbulence in aviation refers to the irregular and often unpredictable movement of air that can affect an aircraft during flight.
- It can range from mild bumps to more severe jolts and can be caused by various factors, such as weather conditions, atmospheric disturbances, and the interaction between different air masses.

### FAA turbulence reporting criteria

Intensity	Aircraft Reaction	Reaction Inside Aircraft
Light	Turbulence that momentarily causes slight, erratic changes in altitude and/or attitude (pitch, roll, yaw). Report as <b>Light Turbulence</b> Or Turbulence that causes slight, rapid, and somewhat rhythmic bumpiness without appreciable changes in altitude or attitude. Report as <b>Light Chop</b> .	Occupants may feel a slight strain against seat belts or shoulder straps. Unsecured objects may be displaced slightly. Food service may be conducted and little or no difficulty is encountered in walking.
Moderate	Turbulence that is similar to Light Turbulence but of greater intensity. Changes in altitude and/or attitude occur but the aircraft remains in positive control at all times. It usually causes variations in indicated airspeed. Report as <b>Moderate Turbulence</b> or Turbulence that is similar to Light Chop but of greater intensity. It causes rapid bumps or jolts without appreciable changes in aircraft altitude or attitude. Report as <b>Moderate Chop</b> .	Occupants feel definite strains against seat belts or shoulder straps. Unsecured objects are dislodged. Food service and walking are difficult.
Severe	Turbulence that causes large, abrupt changes in altitude and/or attitude. It usually causes large variations in indicated airspeed. Aircraft may be momentarily out of control. Report as <b>Severe Turbulence</b> .	Occupants are forced violently against seat belts or shoulder straps. Unsecured objects are tossed about. Food service and walking are impossible.
Extreme	Turbulence in which the aircraft is violently tossed about and is practically impossible to control. It may cause structural damage. Report as <b>Extreme</b> <b>Turbulence</b> .	_

### **Turbulence and its causes**

Turbulence types:

- <u>Convective Turbulence</u>: Caused by alternating currents of warm air rising and cooler air descending.
- <u>Mechanical Turbulence</u>: Caused by wind flowing over irregular terrain or obstructions, or by a marked change in wind speed or direction over a short distance.
- <u>Mountain Wave Turbulence</u>: Caused by air blowing perpendicular across the top of a mountain range. The most dangerous features of mountain waves are the turbulence in and below the rotor clouds.
- <u>Frontal Turbulence</u>: Produced when moving frontal boundaries are combined with convection and strong winds.
- <u>High Altitude Turbulence</u>: Variations in wind speed and direction principally in the vicinity of the jet stream and occurs above 10,000 feet. This is commonly called clear air turbulence (CAT) because of scant, visible evidence of its existence.

#### Strength of convective currents varies with composition of surface

#### Updrafts may cause pilots to overshoot

ROCKY TERRAIN PLOWED GROUND PAVED ROAD

LANDING FIELD

#### Downdrafts may cause pilots to undershoot

#### WHEAT FIELD

#### LANDING FIELD

Surface obstructions cause eddies and other irregular wind movements

#### Buildings near landing areas may cause turbulence

#### Wind flow over mountain ranges produces turbulence

### In a valley or canyon, safest path is on upslope wind side

DOWNDRAFT

SIDE

THE BEST PATH TO FLY THROUGH A CANYON IS ON THE UPDRAFT SIDE. IF THE CANYON IS SLOPED FLY FROM THE HIGH END TO THE LOW END OR OBTAIN ALTITUDE BEFORE FLYING TOWARD THE HIGHER ELEVATION END.

> AVOID THE DOWNDRAFT SIDE

FLY THE UPDRAFT SIDE UPDRAFT

SIDE

The mountains funnel winds into passes and valleys, thus increasing wind speeds and intensifying turbulence (Venturi Effect).

### **Mountain wave**

#### Near a mountain wave, the following conditions can exist:

- Vertical currents of 2,000 FPM 5,000 FPM.
- Turbulence varies from moderate to severe.
- Wind gusts up to 22 kts per hour between waves.
- Altimeter errors of as much as 1,000 feet.
- Icing.

#### Visual indicators of mountain wave:

- Lenticular clouds
- Rotor clouds
- Cap clouds
- Note: adequate moisture must be present for these clouds to form... a wave can be present without cloud formation.

#### Typical cloud formation, main updraft and downdraft in mountain wave

#### **Clouds associated with a mountain wave**

# Mitigating the hazards

- Helicopter pilots operating in mountainous environments require specialized training, experience, and knowledge of the area.
- Pre-flight planning, detailed weather briefings, and understanding local topography are crucial.
- Regular use of Graphical Forecasts for Aviation and other NWS products.
- Give a PIREP for the flight conditions
- ADS-B In (FIS-B and TIS- B)
