A storm chaser measured a wind gust of 65 mph with a handheld anemometer west of Paducah.

Widespread severe thunderstorms developed on the afternoon of the tenth as a weak upper level disturbance ejected overhead northward out of Mexico. The initial activity rapidly developed near the dryline, which was located near the Texas/New Mexico line, late Tuesday afternoon. Aided by strong instability, several of the storms quickly became severe mostly producing severe thunderstorm winds. The thunderstorms gradually evolved into a solid line and tracked eastward across much of the South Plains, Rolling Plains and southern Texas Panhandle through the mid-late evening hours continually producing severe winds. Lastly, a wake low developed in the departing convection which generated a high wind gust of 62 mph near McAdoo measured by the Texas Tech University West Texas mesonet.

CASTRO COUNTY 8.7 E SUMMERFIELD [34.73, -102.35]				
05/11/22	18:45 CST	0	Hail (2.00 in)	
05/11/22	18:45 CST	0	Source: Broadcast Media	

Local broadcast media relayed a report of hail up to two inches in diameter along US Highway 385 in far northern Castro County. No damage was reported.

Scattered thunderstorms again developed on the afternoon of the 11th as a weak upper level short wave approached the area. A deep upper level trough was able to keep a dryline backed up into eastern New Mexico this afternoon. Stronger deep layer shear was able to keep convection discrete on the 11th. One of the storms that developed generated hail up to two inches in diameter in far northern Castro County.

Storm Data and Unusual Weather Phenomena - May 2022					
Location	Date/Time	Deaths & Injuries	Property & Crop Dmg	Event Type and Details	
A Texas Tech University West Texas	mesonet site near Abernathy measured	a severe wind gust o	of 61 mph.		

CHILDRESS COUNTY 0.9 E (CDS)CHILDRESS ARPT [34.43, -100.28]		
05/24/22 02:26 CST	0	Thunderstorm Wind (MG 50 kt)
05/24/22 02:26 CST	0	Source: ASOS

The automated surface observing system at Childress Municipal Airport measured a wind gust of 58 mph.

Returning Gulf of Mexico moisture into the South Plains of West Texas fueled widespread severe thunderstorm development across the region on the afternoon and evening of the 23rd. Moderate to strong instability developed across the western South Plains and eastern New Mexico Monday afternoon and evening as the improving low-level moisture and temperatures warming into the 80s developed beneath an approaching upper level storm system. Relatively strong wind shear caused several of the thunderstorms to rotate as they moved into the western South Plains and western Texas Panhandle. A cluster of thunderstorms moving northeast out of southeastern New Mexico interacted with an outflow boundary moving northwest out of the Permian Basin. This caused a storm on the southern flank of the cluster to begin to rotate and become supercellular and take a more easterly, then southeasterly track. As the storm intensified, it became cyclic in behavior and its forward speed varied from about 5 mph to 20 mph. An NWS storm survey revealed that this supercell produced nine separate tornadoes over an approximately two hour period. The tornadoes occurred over rural areas which limited the overall impacts. Spotty damage did occur including two oil pumpjacks that were toppled by the intense tornadic winds. This damage, along with snapped power poles and flipped center pivots earned a peak damage rating of EF-2. The thunderstorms eventually evolved into a larger complex that brought widespread rain to most of the South Plains, Rolling Plains, and southern Texas Panhandle. The heaviest rain was associated with the slow-moving tornadic storm and was concentrated over Bailey County, where three to as much as seven inches of rain fell.

A large, dusty tornado at 1809 CST near the Cochran/Bailey County line. The picture is courtesy of Kholby Martin.

	05/24/22 18:13 CST	0				

Following severe weather the previous afternoon of the 23rd, another batch of thunderstorms originating from the higher terrain of eastern New Mexico swept through the region. This complex of thunderstorms moved much more quickly than the previous evening's storms, though additional slow-moving storms also formed along a weak frontal zone over the central South Plains late Tuesday afternoon which brought torrential rainfall to a portion of the South Plains. The thunderstorms that formed above the quasi-stationary frontal zone were able to concentrate the spin along the front, which resulted in the development of several landspout type tornadoes. At one point as many as three landspouts were observed at the same time near the community of Meadow (Terry County). The landspouts moved very little, dissipated relatively quickly, and inflicted no known damage. In contrast to the limited and short-lived landspouts, the bulging cluster of storms generated widespread severe wind gusts across the central and southern South Plains. Severe wind gusts developed in the southern South Plains underneath stratiform precipitation well behind the main convective line.

High wind gusts from stratiform precipitation were measured by the Texas Tech University West Texas mesonet shown below:

69 mph at Graham (Garza County), 67 mph at Post (Garza County), and 60 mph at O'Donnell (Lynn County).

A pair of landspout tornadoes near Meadow. The photograph is courtesy of Wood Franklin.

(TX-Z023) SWISHER, (TX-Z026) CHILDRESS, (TX-Z029) HALE, (TX-Z036) CROSBY, (TX-Z042) GARZA						
	05/28/22 16:45 CST	0	High Wind (MAX 65 kt)			
	05/28/22 18:11 CST	0				

Broad upper troughing over the Great Basin deepened and moved eastward resulting in backing southwest flow aloft. Surface winds veered and increased in response to strong lee-side cyclogenesis over eastern Colorado, sharpening a modest dryline which moved into the Rolling Plains. A weak upper level disturbance over northern Mexico approached the area and resulted in isolated high based convection. A very dry and hot lower atmosphere contributed to strong DCAPE values this afternoon and resulted in virga showers producing severe wind gusts. Updrafts were weak enough that very little to no lightning was observed with this convection.

High wind reports from the Texas Tech University West Texas mesonet are below:

75 mph at White River Lake (Crosby County),
73 mph at Childress (Childress County),
68 mph at Tulia (Swisher County),
62 mph at Graham (Garza County), and
59 mph at Vigo Park (Swisher County).

Local broadcast media relayed a report of qu	arter size hail in Floydada.			

Abundant moisture, in combination with strong daytime heating, provided the fuel for robust thunderstorm development along a quasi-stationary front located across the southern Texas Panhandle late on the afternoon of the 31st. Strong instability and moderate wind shear allowed the storms which formed to quickly become severe and gain mid-level rotation. The rotating storms were efficient at generating hail, including very large hail at times. Several locations near Memphis (Hall County) and Tulia (Swisher County) reported hail as large 3 to 3.5 inches in diameter. The giant hail, bigger than baseballs, destroyed windshields on numerous vehicles on US Highway Highway 287 in Hall County. The intense and excessive rainfall flooded out a number of roadways across the southeast Texas Panhandle, including in and around Memphis. This event carried over into the early morning hours of June first.
