- Ice Accumulation: Few hundredths of an inch of ice accretion possible late Friday Night (after midnight) through late morning Saturday for areas north and west of NYC. With subfreezing ground temperatures expected in these areas Friday Night, this would result in dangerous travel with icing on untreated and elevated surfaces.
- Highest probability of ice accretion for areas north of I-80, I-287, I-684, and I-84 (50-60%) probability).
- Patchy ice accretion possible as far south as the I-95 in CT depending on timing of precipitation onset (5-10% probability).
- **Temperatures:** Upper 20s to 32 F Friday Eve into the overnight, gradually rising above freezing by mid to late Saturday morning for most places. Interior valleys could hover around freezing through around midday.
- Thereafter, periods of plain rain expected for all areas Saturday afternoon through the weekend.
- Hazardous Weather Outlook Winter Weather Advisories will be issued late tonight or Friday if confidence in ice accretion increases.
- Timing of onset of freezing rain Friday Night (most likely between midnight and 4am) with light precipitation and an initially dry airmass.
- How guickly surface temps rise above freezing across the interior, particularly across valleys locations with a light wind flow. Perhaps as late as midday Saturday.

By 6AM Friday.
