

# Model State Updating, VAR Project, Where do we want to go?

D.-J. Seo

Hydrology Laboratory  
National Weather Service  
DOH Conference, June 9, 2004  
Silver Spring, MD

# The Big Picture

Global coupled ocean-land surface-atm. model

Regional coupled land surface-atm. model

Uncoupled land surface model

Precipitation, temperature, humidity, surface pressure, wind, insolation

Groundwater model

Groundwater level

Soil moisture, snowpack

(Uncoupled) Rainfall-runoff, snow models

Routing models

Streamflow, stage

Reservoir models

Reservoir level, temperature

Hydraulic models

Flow, stage, velocity, temperature

Estuary models

Sea level, wind, pressure, temperature

# Where do we want to go?

- Comprehensive soil and surface-water data assimilation for monitoring and prediction of terrestrial water in the ensemble paradigm
- Close the terrestrial water budget as closely as possible across scale
- Produce the “best” analysis of **soil** and **surface** water storage and flux/flow with uncertainty information
  - Reanalysis capability
- Provide more accurate initial and boundary conditions for (ensemble) forecast runs
- Help understand model errors, improve model physics and uncertainty modeling
- Help identify, assess and quantify observational/data needs (in-situ and remotely sensed)

# The VAR Project

- A small but important piece in the comprehensive DA system
- Runoff production from headwater basins is subject to large input uncertainty (e.g. precipitation) and hydrologic uncertainty (model states, model errors)
- Test and improve a methodology (variational assimilation) in an operational environment
- Demonstrate operational worthiness

# DA methodologies

- Variational assimilation (VAR)
- Ensemble Kalman filter/smoothen (EKF/S, sequential assimilation)
- They are, under certain conditions, the same
- Depending on the nature of the problem, one may be better-suited than the other
- VAR is good for development (variational or sequential) and piecewise DA
- EKF/S is better-suited for end-to-end ensemble DA

# Near-term plan

- Evaluate and improve VAR for lumped 1-hr SAC-UH (see Bob Corby's presentation)
- Generate and present verification statistics
- Develop a prototype state updating for HL-RMS (see illustration)
- Start R&D for assimilation of soil moisture (and other observations)
- Develop a comprehensive DA science plan (a product of the NWS Integrated Water Science Plan)

# Mid-term plan for VAR

- Continue science validation through HOSIP
- Initiate operational software development through HOSIP

# In closing

- VAR
  - a DA tool for headwater basins
  - a small but important piece in the terrestrial water DA system
  - Being experimented at WGRFC for science validation
- A comprehensive DA science plan to be developed
  - To include DA strategies for ESP, snow, site-specific, distributed, routing, hydraulic and reservoir models

# State Updating for RMS – An illustration
